# CS 61A Fall 2016

# Structure and Interpretation of Computer Programs

MIDTERM 2

#### INSTRUCTIONS

- You have 2 hours to complete the exam.
- The exam is closed book, closed notes, closed computer, closed calculator, except one hand-written  $8.5" \times 11"$  crib sheet of your own creation and the official CS 61A study guides.
- Mark your answers on the exam itself. We will not grade answers written on scratch paper.

#### 1. (8 points) Halloween (All are in Scope: WWPD, Object-Oriented Programming, Linked Lists)

For each of the expressions in the table below, write the output displayed by the interactive Python interpreter when the expression is evaluated. The output may have multiple lines. If an error occurs, write "Error", but include all output displayed before the error. The Link class appears on page 2 of the midterm 2 study guide.

The first two rows have been provided as examples.

Recall: The interactive interpreter displays the value of a successfully evaluated expression, unless it is None. Assume that you have started python3 and executed the following statements:

```
class Party:
    guests = Link.empty
    def __init__(self, time):
        Party.guests = Link(time+1, Party.guests)
    def attend(self):
        self.guests.rest = Link(self.guests.rest)
        return self.guests
class Costume(Party):
    def __init__(self, bow, tie):
        Party.guests.rest = Link(bow)
        self.ie = Link(self)
    def attend(self):
        print(repr(self.ie))
        Party.attend = lambda self: Party(9).guests
    def __repr__(self):
        print('Nice')
        return 'Costume'
```

Expression	Interactive Output
Link(1, Link.empty)	Link(1)
Link(1, Link(2))	Link(1, Link(2))
Party(1).guests	
Party(3).attend()	
Costume(5, 6).attend()	
Party(7).attend()

## 2. (8 points) A List with a Twist (At least one of these is out of Scope: Environment Diagrams, Nonlocal, Python Lists)

Fill in the environment diagram that results from executing the code below until the entire program is finished, an error occurs, or all frames are filled. You may not need to use all of the spaces or frames.

A complete answer will:

- Add all missing names and parent annotations to frames.
- $\bullet$  Add all missing values created or referenced during execution.
- Show the return value for each local frame.
- Use box-and-pointer notation for list values. You do not need to write index numbers or the word "list".

1 2 3 4 5 6 7 8 9 10 11	<pre>lamb = 'da' def da(da):     def lamb(lamb):         nonlocal da         def da(nk):             da = nk + ['da']             da.append(nk[0:2])             return nk.pop()         da(lamb)     return da([[1], 2]) + 3</pre>	Global frame	[parent=]
12	da ( cambaa da . da ( camb) )		Return Value
		f2:	[parent=]
			Return Value
		f3:	[parent=]
			Return Value
		f4:	[parent=]
			Return Value

## 3. (6 points) Return Policy (At least one of these is out of Scope: Nonlocal, Python Lists, Mutability)

Implement quota, which takes a one-argument function f and a non-negative integer limit. The function it returns has the same behavior as f, except that each value is only returned up to limit times. After that, the function returns an "Over quota" message instead, and the limit is decreased by 1 for future calls.

```
def quota(f, limit):
   """A decorator that limits the number of times a value can be returned.
   >>> square = lambda x: x * x
   >>> square = quota(square, 3)
   >>> square(6)
                            # 1st call with return value 36
   >>> [square(5) for x in range(3)] # 3 calls when the limit is 3
   [25, 25, 25]
   >>> square(5)
                            # 4th call with return value 25
   'Over quota! Limit is now 2'
   >>> square(-6)
                            # 2nd call with return value 36
   36
   >>> square(-6)
                            # 3rd call when the limit is 2
   'Over quota! Limit is now 1'
   >>> square(7)
                            # 1st call when the limit is 1
                            # 5th call with return value 25
   >>> square(5)
   'Over quota! Limit is now 0'
   values = []
   def limited(n):
     y = _____
      count = len(_____)
     values.append(y)
      if _____:
     limit = ______
     return 'Over quota! Limit is now ' _____
   return limited
```

### 4. (6 points) A Classy Election (All are in Scope: Object-Oriented Programming)

Implement the VotingMachine and Ballot classes based on the doctest below. The voting machine must determine which choice has the most votes (the winner) and detect if a ballot is used more than once. In case of a tie, the winner among choices with maximal votes is the one that most recently received a vote. Ballot.vote takes a string, and a VotingMachine must handle an arbitrary number of choices.

class VotingMachine: """A machine that creates and records ballots. >>> machine = VotingMachine(4) >>> a, b, c, d = machine.ballots >>> d.vote('Bruin') 'Bruin is winning' >>> b.vote('Bruin') 'Bruin is winning' >>> c.vote('Bear') 'Bear is losing' >>> a.vote('Bear') 'Bear is winning' >>> c.vote('Tree') 'Fraud: multiple votes from the same ballot!' >>> machine.winner 'Bear' 11 11 11 def \_\_init\_\_(self, k): self.ballots = [\_\_\_\_\_ for i in range(k)] self.votes = {} def record(self, ballot, choice): if ballot.used: return 'Fraud: multiple votes from the same ballot!' self.votes[choice] = \_\_\_\_\_\_ + 1 if \_\_\_\_\_: return choice + ' is losing' else: return choice + ' is winning' class Ballot: def \_\_init\_\_(self, machine): self.machine = machine def vote(self, x):

return \_\_\_\_\_

### 5. (6 points) Trick or Tree (All are in Scope: Trees, Linked Lists)

Implement path, which takes a linked list s and a Tree instance t. It returns whether s is a path from the root of t to some leaf. The Tree and Link classes are on page 2 of the midterm 2 study guide.

#### Restrictions:

- You may not call the built-in len function on a linked list or invoke its \_\_len\_\_ method.
- You may not apply element selection (e.g., s[2]) on a linked list or invoke its \_\_getitem\_ method.

```
def path(s, t):
  """Return whether Link S is a path from the root to a leaf in Tree T.
   >>> t = Tree(1, [Tree(2), Tree(3, [Tree(4), Tree(5)]), Tree(6)])
   >>> a = Link(1, Link(3, Link(4)))  # A full path
  >>> path(a, t)
   True
  >>> b = Link(1, Link(3))
                             # A partial path
  >>> path(b, t)
   >>> c = Link(1, Link(2, Link(7))) # A path and an extra value
   >>> path(c, t)
  False
   >>> d = Link(3, Link(4))
                            # A path of a branch
   >>> path(d, t)
   False
  if _____:
      return False
  if _____:
      return True
   return _____([______ for b in t.branches])
```

Name:

6. (6 points) Left it Right There	6.	(6	points)	) Left	it	Right	There
-----------------------------------	----	----	---------	--------	----	-------	-------

(a) (4 pt) (All are in Scope: Trees) Implement binary, which takes a list s of unique integers. It returns a binary search tree containing all of those integers, represented as a BTree instance or BTree.empty. The values in any path of this tree must appear in the same order as they did in s. The BTree class is on page 2 of the midterm 2 study guide.

return BTree(root, binary(left), binary(right))

(b) (1 pt) (All are in Scope: Asymptotic Notation) Circle the  $\Theta$  expression that describes the smallest possible height of the tree returned by binary(s) for a list s of length n. The height of a tree is the length of the longest path from its root to a leaf.

 $\Theta(1)$   $\Theta(\log n)$   $\Theta(n)$   $\Theta(n^2)$  None of these

(c) (1 pt) (All are in Scope: Asymptotic Notation) Circle the Θ expression that describes the largest possible height of the tree returned by binary(s) for a list s of length n. The height of a tree is the length of the longest path from its root to a leaf.

 $\Theta(1)$   $\Theta(\log n)$   $\Theta(n)$   $\Theta(n^2)$   $\Theta(2^n)$  None of these

#### 7. (10 points) Summer Camp

(a) (6 pt) (All are in Scope: Tree Recursion, Python Lists) Implement sums, which takes two positive integers n and k. It returns a list of lists containing all the ways that a list of k positive integers can sum to n. Results can appear in any order.

```
can appear in any order.
def sums(n, k):
   """Return the ways in which K positive integers can sum to {\tt N}.
   >>> sums(2, 2)
   [[1, 1]]
   >>> sums(2, 3)
   >>> sums(4, 2)
   [[3, 1], [2, 2], [1, 3]]
   >>> sums(5, 3)
   [[3, 1, 1], [2, 2, 1], [1, 3, 1], [2, 1, 2], [1, 2, 2], [1, 1, 3]]
      return _____
   y = []
   for x in _____:
      return y
(b) (4 pt) (All are in Scope: Python Lists, Lambda Expressions) Why so many lines? Implement f and g for
  this alternative version of the sums function.
f = lambda x, y: (x and [____ for z in y] + f(____, ___)) or []
def sums(n, k):
   """Return the ways in which K positive integers can sum to N."""
   g = lambda w: (w and f(_____)) or [[]]
   return [v for v in g(k) if sum(v) == n]
```
